ABSTRACT

This paper reports a screening results of the secondary metabolites composed in *Spathodea campanulata* Beauv stem bark, evaluate inhibiting activity of malondialdehyde (MDA) on rat's cancer model exposed with benzopyrene, and the histology of its lung. The secondary metabolite of the stem bark fraction consisted of alkaloids, flavonoids-phenolic, terpenoid and steroid compounds. The isolated fraction contained of these metabolites significantly indicate bioactivity by reducing of malondialdehyde (MDA) level, and also histology appearance of the lung tissue prepared from the benzopyrene-exposed rat indicated a curative activity.

Keywords: *angsret, malondialdehyde, mda, natural product, secondary metabolite, Spathodea campanulata*

INTRODUCTION

Lung cancer has been much attention as its increasing prevalence globally. It has caused mortality and morbidity both on man and woman [1, 2]. Smoking was reported gave about 80% contributions [3-5]. The tobacco smoke content such as benzo[a]pyrene [6] and other aromatic or poly-aromatics from a cigarette burning products which were able to cause lung cancer including squamous-cell carcinoma, small-cell carcinoma, adenocarcinoma (including bronchiolar or alveolar carcinoma) and large cell carcinoma [5].

The on going research in order to explore the potency of Indonesian indigeneous plant has focused on *S. campanulata* Beauv (family Bignoniaceae) [7]. Found as a high plant with orange flower habitat for some rare bird species in Merubetiri National Conservation area, South Banyuwangi forest [8]. The local name is *angsret* (East Java), *kiengsrot* (Aceh), *kayu perahu* (Kalimantan), *sepatu diat* (Melayu), *kacret-kacretan* (Bali), *Kiancret* (Jakarta) and *kecrutan* (Malang). It has also widely been used for city garden plants, to build wood-boat, and part of its plants such as stem bark and aerial parts was reported as traditional medicine, anti-malarial, antibacterial, anti inflammatory, and antiviral

[9-13, 15-17]. Recently, we found a non-polar fraction of stem bark contained triterpenoids compounds strongly inhibit bacterial growth and this paper is disclosed a malondialdehyde level reduction and curative activity of stem bark's extract fraction on a rat exposed with benzo[a]pyrene, and also the histology of lung tissue [14, 18].

MATERIALS AND METHODS

Chemicals

All chemicals used has analytical reagent grade (or as mentioned); ethanol (Bratachem), ethyl acetate (Bratachem) and n-hexane (Bratachem) was applied after purification and drying process following standard purification and drying methods for organic solvent. Mercury chloride (Merck), potassium iodide (Merck), iodine (Sigma), hydrochloric acid (Smart Lab), sulphuric acid (Smart Lab), bismuth nitrate (Sigma), magnesium powder (Sigma), and iron(III) chloride (Smart Lab). A malondialdehyde test kit, and a kit for histology observation.

Plants sample preparation

The plant sample was collected from Brawijaya University garden and identified by drs. Djati Batoro in the Laboratory of Taxonomy, University of Brawijaya. Amounts 3.0 kg of air-dried and grinded stem bark was macerated with methanol (FMeOH). The isolate fraction of ethyl acetate (FEA) and n-hexane (FnH) was

afforded from partition of methanol extract after solvent evaporation. Then, each isolate fraction was stored in freezer before application.

Procedure for secondary metabolite evaluation

The presence alkaloid was clarified using Meyer reagent, Dragendorff reagent, and Wagner test. Mayer test: Extract methanol of stem bark (1 mL) was added a Mayer reagent (mixture of solution 1.3 g of mercury (II) chloride in 50 mL aquadest and solution of 5 g potassium iodide in 50 mL aquadest). A white precipitate is indicated as an alkaloid. Dragendorff test: Methanol extract of stem bark (1 mL) was added a few drop of concentrated hydrochloric or sulphuric acid, and Dragendorff reagent (a mixture of solution potassium iodide 8 g in 20 mL aquadest and solution bismuth nitrate 1 g in 50 mL aquadest). The presence of alkaloid was indicated as orange precipitation. Wagner test: Methanol extract of stem bark (1 mL) was added Wagner reagent (a mixture of iodide 1.5 g and 2 g potassium iodide in 10 mL aquadest). Positive test for alkaloid was indicated as brown precipitate.

Flavonoid test was undertaken using Shinoda test conducted by addition of ethanol (5 mL) to the sample (100 mg), and then it was added magnesium powder and a few drop of concentrated hydrochloric acid. The presence of flavonoid indicated color as orange (flavonoid), red (flavonol), and purple (xanthone). Flavonoid could react with sulphuric acid to give a dark yellow or red-blue (chalcone, aurone), orange-red (flavonone).

Phenolic compounds were tested using air dry stem bark (100 mg), and extracted with methanol. The resulted extract was added solution iron (III) chloride 1%. The presence of phenolic compound was indicated when the solution turn to violet or green-black.

Terpenoid and steroid test was conducted according to Lieberman-Burchard test and Salkowski test [20, 21]. The Lieberman-Burchard test was performed by addition of sample (2 mL) with a few drops of concentrated sulphuric acid and acetic anhydride. The presence of terpenoid was indicated with color blue, red and violet. Salkowski test was performed by addition of methanol extract sample (2 mL) with chloroform (1 mL), and concentrated sulphuric acid (1 mL) [21]. The presence of red or orange indicated terpenoid steroid compounds.

Animal treatment

The standard procedure was conducted using animal as research model has met the ethical clearance

procedure in Brawijaya University. The prepared animal with pre-cancer was conducted according to [22]. The *Rattus novergicus* rat species was divided into 5 groups: first group consists of healthy mice as control, and second group contained mice exposed with benzopyrene and groups three to five composed mice-exposed benzopyrene with different treatments using isolate fraction of n-hexane (FnH), ethyl acetate (FEA), and methanol (FMeOH). For groups of benzopyrene-exposed mice were injected intraperitoneally with benzopyrene solution (1.0 g benzopyrene dissolved in 5.0 mL of corn oils) using doses 200 mg/kg of body weight. The injection was repeated 4 times and incubated for 30 days after the last injection [23]. After the incubation time, three groups of mice exposed benzopyrene were treated with FnH, FEA, and FMeOH. Sample of FnH and FEA was prepared by dissolving in corn oils (200 µL) and aquadest (1800 µL), while for FMeOH was dissolved in aquadest (2.0 mL). The injection of each group was performed 7-times (doses 100 mg/kg of body weight) for 7 day and incubated for 30 days. Then, mice were sacrificed and the lung was prepared for histology using haematoxyline-eosin (HE) method and malondialdehyde (MDA) analysis.

Malondialdehyde standard curve

A kit of malondialdehyde with variation concentration (0; 1.0; 2.0; 3.0; 4.0; 5.0; 6.0; 7.0; and 8.0 µg/mL) was pipetted (100 µL) in reaction tube and each was dissolved with aquadest (550 µL). Each of tube was added standard trichloroacetic acid (100 µL, 100%), hydrochloric acid (250 µL, 1.0 M), and sodium thiobarbiturate (100 µL, 1.0%). The homogenized of these solutions were centrifuged at 500 rpm for 10 min, wrapped with plastic, and incubated in waterbath (100°C) for 30 min. After cold at room temperature the samples were taken for quantitative MDA analysis using spectrophotometer (λ max 533 nm).

Malondialdehyde measurement

The homogenized mixture of lung tissue (0.45 g) and a cold sodium chloride solution (1.0 mL, 1.0%) was centrifuged at 8000 rpm for 20 min to afford supernatant. A 100 µL of this supernatant in reaction tube was added aquadest (550 µL), trichloroacetic acid, TCA (100 µL, 10%) and was further homogenized. This mixture was added hydrochloric acid (250 µL, 1.0 M), sodium thiobarbiturate (250 µL) and re-homogenized, centrifuged at 500 rpm for 10 min to result supernatant. The resulted supernatant was incubated in waterbath (100°C) for 30 min, further centrifuged to

afford supernatant, and prepared for analysis using spectrophotometer (λ_{max} 533 nm). The absorbance resulted was plotted in malondialdehyde curve standard to calculate the concentration.

RESULTS AND DISCUSSION

Phytochemical analysis of *S. campanulata* Beauv stem bark using secondary metabolite's visualization reagent indicated a diverse group of compound composed the stem bark. The hexane fraction contained phenolic, steroid and terpenoid compounds. Meanwhile for both ethyl acetate and methanol fraction was composed with similar class of secondary metabolite such as alkaloid, flavonoid, phenolic, saponin, steroid, and terpenoid (Figure 1 A).

equilibrium quantity for normal cell [24, 25]. This level up of ROS can promote cell mutation, DNA mutation, and lead on the failure of cell differentiation or cancer initiation [26]. Conversely, the inhibition of ROS concentration in cell can be expressed with the reduction of the MDA in cell [27-29].

The result gave positive affect that all of the isolate fractions reduced the MDA concentration on the rat's model which was exposed using benzopyrene (BP). The highest lowering MDA concentration when it was treated using hexane isolate fraction (FnH). The MDA value reduced to 0.3408 $\mu\text{g/mL}$ (or decreased by 50%). In similar word, this fraction was able to inhibit more than 50% reactive oxygen species in cell [27-29]. While for isolate fraction from ethyl acetate (EA) and

Figure 1. **A.** Phytochemical screening of *S. campanulata* Beauv stem bark. **B.** MDA concentration of the healthy rat (HR), rat exposed benzopyrene (BP), rat with treatment using FnH (rat exposed benzopyrene treated with hexane fraction), EA (rat exposed benzopyrene treated with ethyl acetate fraction), and MeOH (rate exposed benzopyrene treated with methanol fraction).

Semi-clinical evaluation using rat's model for cancer by exposing it with benzopyrene gave a significant feature. Increasing MDA concentration in cell as normal or healthy rat (0.2026 $\mu\text{g/mL}$) to 0.6835 $\mu\text{g/mL}$ as important indication the affect of benzopyrene on cell (Figure 1 B). This was also a signal increasing the number of reactive oxygen species (ROS) in cell where ROS in cell such as peroxide, hydroxyl radical, and radical oxygen group presence at

methanol (MeOH) was able to inhibit about 30% of ROS. Comparing to the healthy rat (MDA concentration was 0.2026 $\mu\text{g/mL}$), the isolate fraction from hexane significantly has a close value on it. This isolate fraction basically could heal the sick cell on lung tissue. Further observation toward curative activity on lung tissue was undertaken using histology observation. The result is presented in Figure 2 and 3.

Figure 2. **A.** Hystology of rat's lung. Healty rat as a negative control. **B.** Sick rat which was exposed with benzopyrene 200 mg/Kg of body weight..Hystology of lung's rat exposed with benzopyrene after treatment with isolate fraction of *S. campanulata* stem bark. **C.** FnH, n-hexane, **D.** FEA, ethyl acetate, **E.** FMeOH, methanol.

The affect an intraperitoneal injection of benzopyrene on rat histologically could damage cell in lung tissue [23]. Figure 2 B displays its histology result. Cell disintegration and covered by yellow block due to cell mutation, differentiation, and cancer was observed. This consistent with previous result that benzopyrene could increase ROS quantity in cell. This increase can damage the cell itself, and also the MDA concentration in cell going up. While in the lung tissue of healthy rat which was not exposed with benzopyrene indicates a solid cell, no disintegration and differentiation was observed (Figure 2 A).

Oral treatments with isolate fractions prepared (dose 100 mg per kilogram of rat's body weight) was undertaken using some groups of sick rat exposed with benzopyrene, and these were following by incubation for 30 day. The histology result of lung tissue as display in figure 2. All of the isolate fractions provide better a cell solidity compare to cell of sick rat (Figure 2 B). This result reveals that all of the isolate fractions were able to cure the damage, injured, or disintegrated of cell.

The best visual observation was on that was treated using hexane's isolate fraction. It seemed disintegration of cell was not occured. Cell completely solid, no hole inside cell was observed, and appeared similar to the healthy cell as it in Figure 2 A. With this result, it is

believed that compound composed hexane's isolated fraction responsible in restoring the damage cell. The phenolic, steroid and terpenoid compounds of secondary metabolite possibly able to cure the cell disintegration. Even though the mechanism undergone was not clear yet, it is believed correlate to inhibition during the formation of reactive oxygen species (ROS) by reducing MDA concentration.

CONCLUSIONS

The curative activity of *S. campanulata* Beauv stem bark isolate fraction on rat's model for lung cancer was found. It was observed as reduction activity of MDA concentration on cell, and its histology appearance of lung's tissue. Moreover, some important groups of secondary metabolite responsible isolated for this was phenolic, steroid, and terpenoid compounds.
